# Components of Inventory Change And Rental Market Dynamics: Miami-Ft. Lauderdale 1995-2002 

February 2005

Econometrica, Inc. under contract to:

U.S. Department of Housing and Urban Development Office of Policy Development and Research

Principal Authors: Frederick J. Eggers \& Fouad Moumen

## Acknowledgements

This report was produced by Econometrica, Inc., under Contract No. GS-10F-0269K, for the U.S. Department of Housing and Urban Development (HUD). Cyrus Baghelai served as Econometrica’s Project Director, and the primary analyses and report writing were performed by Frederick J. Eggers and Fouad Moumen. The authors thank David A. Vandenbroucke, the HUD Government Technical Representative, for many helpful suggestions and for his assistance in obtaining needed information from the Census Bureau. The authors also thank Gregory J. Watson of ICF Consulting for assistance in solving the weighting problem, and Dennis Schwanz of the Census Bureau for commenting on the proposed weighting.

# Components of Inventory Change and Rental Market Dynamics: Miami-Ft. Lauderdale 1995-2002 

## Overview

Housing analysts use two techniques-Components of Inventory Change (CINCH) and rental market dynamics-to look at a housing market at two points in time and explain how the observed changes came about in physical (bricks and mortar) terms. CINCH focuses first on the overall number and then the characteristics of units at different times. Using CINCH methods, analysts answer such question as: "What happened to the x units that disappeared from the housing stock between the beginning and the end of the period?" or "Where did the increase in owner-occupied units come from?" Rental market dynamics, which is really a type of CINCH analysis, focuses on the rental market with particular emphasis on the affordability of rental housing. Using rental market dynamics techniques, analysts answer such questions as: "Have the number of rental units affordable to households with very low incomes increased or decreased over the period?" or "What happened to the units that were affordable to low-income households at the beginning of the period?"

Previously HUD commissioned CINCH and rental market dynamics analyses using the national American Housing Survey (AHS). ${ }^{1}$ This report focuses on the Miami-Ft. Lauderdale metropolitan housing market over the period between 1995 and 2002. It is one of 13 reports based on local American Housing Surveys conducted in 2002; these 13 metropolitan areas were previously surveyed in either 1994 or 1995.

CINCH and rental market analysis have both forward-looking and backward-looking components. In the forward-looking components, analysts start with the housing stock available at the beginning of the period and then, looking at the end of the period, attempt to explain what happened to those units. Possible answers include some units still exist and serve the same market, some units still exist but serve a different market, some units have been demolished or destroyed in natural disasters, or some units are being used for nonresidential purposes. In the backward-looking component, analysts start with the housing stock available at the end of the period and, looking at the beginning of the period, attempt to explain where those units came from. Possible answers include some units existed at the beginning of the period and served the same market, some units existed at the beginning of the period but served a different market, some units were newly constructed over the period, or some units were being used for nonresidential purposes at the beginning of the period. Neither CINCH nor rental market dynamics try to track the experience of a unit over the entire period; both are interested only in the beginning and the end of the period. For example, a housing unit in 1995 may have become a medical office in 1997, but returned to being a housing unit in 2000. CINCH

[^0]would record this unit as having undergone no change over the period from 1995 to 2002. In classical analytical jargon, CINCH and rental market dynamics are comparative static analyses.

Ideally one would want to combine the forward-looking and backward-looking analyses to produce a complete accounting that can explain the beginning and the end consistently in terms of units that existed in both periods, losses from the stock over the period, and additions to the stock over the period. The analysis in this report uses the AHS, which is a sample of units at both points in time; and, unfortunately, previous efforts using the AHS have demonstrated that creating sample weights that take both periods into account generates some inconsistent or inaccurate results. For this reason, the most recent analyses have separated the forwarding-looking and backward-looking components. This report will do the same. (Weighting is explained briefly in Appendix B and more fully in a separate paper cited in the Appendix.)

The remainder of this report consists of four sections:

- An explanation of how to read the CINCH tables.
- Two sets of four tables each: a set of forward-looking tables tracing the movement of units from 1995 to 2002 and identifying how units were lost to the housing stock; and a set of backward-looking tables tracing where 2002 units came from and distinguishing between units that were part of the stock in 1995 and units that were additions to the stock since 1995.
- A brief discussion of the rental market dynamics.
- Two rental market dynamics tables, one forward-looking and one backwardlooking.

At various places, the discussion points out some of the limitations of these analyses or of using the AHS metropolitan samples for these analyses.

Two appendixes explain how the results were tested and how the weights were created.

## How to Read CINCH Tables

Rows and columns serve different purposes in CINCH tables. The rows identify classes of units to be analyzed. The columns trace those units either forward or backward.

The forward-looking tables are concerned with what happened to the 1995 housing stock by 2002. There are three basic dispositions of 1995 units: units that continue to exist in 2002 with the same characteristics (or serving the same market), units that continue to exist in 2002 but with different characteristics (or serving a different market), and units that were lost to the stock.

The backward-looking tables are concerned with where the 2002 housing stock came from in reference to 1995. There are three basic sources of 2002 units: units that existed in 1995 with the same characteristics (or serving the same market), units that existed in 1995 but with different characteristics (or serving a different market), and units that are additions to the housing stock.

Since the essence of the CINCH analysis is in the columns, we will explain the columns in detail.

## Columns Common to Both Forward-Looking and Backward-Looking Tables:

- The first and last columns contain the row numbers. The row numbers are identical for the same tables in the forward-looking and backward-looking sets.

Columns A through E set up the analysis and track units that exist in both periods.

- Column A specifies the characteristic that defines the subset of the stock that is being tracked forward or backward in a particular row. For example, row 2 of Table 1 focuses on occupied units; row 15 focuses on units built in 1985 through 1989.
- Column B gives the estimate published in the AHS report for the number of units that satisfy the conditions specified in column A. For example, the 1995 AHS report for Miami-Ft. Lauderdale counted 1,245,200 occupied units (column B, row 2, Forward-Looking Table 1); the 2002 AHS report counted 1,434,200 occupied units (column B, row 2, Backward-Looking Table 1).
- Column C gives the CINCH estimate of the number of units that satisfy two conditions: (a) being part of the housing stock in the relevant year (1995 for the forward-looking tables and 2002 for the backward-looking tables); and (b) satisfying the condition in column A. CINCH uses different weights than those used in preparing the published reports. Therefore, CINCH estimates can differ from AHS estimates for particular subsets of the housing stock. As explained in Appendix B, the weights were created to match AHS published totals for rows 2 through 4 of Table 1. This perfect match will not be true of other rows. ${ }^{2}$ In the case of the Miami-Ft. Lauderdale metropolitan area, the CINCH weights produce estimates close to the published estimates with a few exceptions. Both ForwardLooking Table 1 and Backward-Looking Table 1 underestimate the number of units built after 1989, and Backward-Looking Table 4 underestimates the number of owner-occupied units with low housing costs.

[^1]- Column D is the CINCH estimate of the number of units from column $C$ that (a) are also part of the housing stock in the other year, and (b) continue to belong to the subset defined by column A. For example, column D of row 2 of ForwardLooking Table 1 estimates that 1,123,310 of the occupied units were occupied in 2002.
- Column E is the CINCH estimate of the number of units from column C that (a) are also part of the housing stock in the other year, but (b) no longer belong to the subset defined by column A. Column E of row 2 indicates that 103,400 units that were occupied in 1995 are still part of the housing stock in 2002 but are no longer occupied. In some cases, the analysis will not allow a unit to change characteristics between the base year and the other year. Examples include type of structure, year built, and number of stories-characteristics that are considered impossible or unlikely to change.

## Columns Unique to Forward-Looking Tables

In forward-looking tables, columns F through K track what happened to units that were lost from 1995 to 2002.

- Column F is the CINCH estimate of the number of units from column C that are not in the 2002 housing stock because they were merged with other units or converted into multiple units. Among occupied units, 1,180 units were lost to mergers and conversions.
- Column G is the CINCH estimate of the number of mobile homes from column C that were moved out during the period. Among occupied units, no mobile homes were moved out.
- Column H is the CINCH estimate of the number of units from column C that became nonresidential at the end of the period. For example, a real estate firm, a tax preparation office, a palm reader, or some other business might buy or rent a house to use for business rather than residential purposes. ${ }^{3}$ Among occupied units, 3,150 became nonresidential.
- Column I is the CINCH estimate of the number of units from column C that were demolished or were destroyed by fires or natural disasters by 2002. In this case, 7,080 units were demolished or destroyed.
- Column J is the CINCH estimate of the number of units from column C that by 2002 were condemned or that were no longer usable for housing because of extensive damage. Among occupied units, 1,180 units are no longer usable for housing.

[^2]- Column K is the CINCH estimate of the number of units from column C that were lost by 2002 for other reasons. These include units that the Census Bureau eliminated for sampling purposes and other miscellaneous losses. Among occupied units, there were 5,900 units lost for these miscellaneous reasons.

The columns form a closed system. Column C counts the number of units tracked; columns D through K account for all the possible outcomes. Therefore, column C minus the sum of columns D through K always equals zero, except for rounding. ${ }^{4}$

## Columns Unique to Backward-Looking Tables

In backward-looking tables, columns F through I track where units came from that are part of the housing stock in 2002, but were not part of the housing stock in 1995. ${ }^{5}$

- Column F is the CINCH estimate of the number of mobile homes from column C that were moved in during the period. Among occupied units, 2,240 mobile homes were moved in (column F, row 2 of Backward-Looking Table 1). ${ }^{6}$ Moveins are treated as additions to balance the treatment of move-outs as losses.
- Column $G$ is the CINCH estimate of the number of units from column $C$ that had been nonresidential in 1995. Among occupied units, 750 had been nonresidential.
- Column H is the CINCH estimate of the number of units from column C that were newly constructed between 1995 and 2002. Among occupied units, 116,910 units were newly constructed.
- Column I is the CINCH estimate of the number of units from column C that were added by 2002 for other reasons. These include units that were considered temporary losses because occupancy was prohibited in 1995 or the interior of the unit was exposed to the elements, and also units that the Census Bureau considered temporarily lost to the housing stock for reasons "not classified." Among occupied units, 3,360 had been temporarily lost to the stock in 1995.

[^3]
## Table 1

Table 1 focuses on the general housing characteristics of the stock. Row 1 provides the highest level CINCH overview of the stock. For this row, column A specifies no conditions other than being part of the stock in the relevant year.

Rows 2-4 divide the housing stock by use. By Census Bureau definition, the number of occupied non-seasonal units equals the number of households. Because households are the basis for all the analyses in Tables 2 through 4, it is important to get a good starting point for these estimates. For this reason, the weights are designed to match published AHS totals for occupied units, vacant units, and seasonal units.

Rows 5-12 divide the housing stock by type of structure to identify what type of units account for losses. ${ }^{7}$ The Census Bureau sometimes suppresses data to protect the confidentiality of respondents. For some metropolitan areas, suppression results in zero estimates for certain multiunit structures in the public data file, whereas the published tables contain estimates for these multiunit classes.

Rows 13-23 divide the housing stock by year built. ${ }^{8}$ The published reports use the categories 1990-1994, 1995-1999, and 2000-2004; we use 1990-1995 and 1996-2002 to isolate units newly constructed since the previous AHS survey. ${ }^{9}$ While only 0.6 percent of all units were demolished or destroyed between 1995 and 2002, 5.6 percent of those built in the 1920s were demolished or destroyed.

Rows 24-30 and 31-35 divide the housing stock by two different measures of interior space, the number of rooms and the number of bedrooms. ${ }^{10}$

Rows 36-41 focus on multiunit structures only and divide them by number of stories. Column E is forced to be zero and, depending on the metropolitan area, the Census Bureau may suppress information, forcing some rows to be zero.

Rows 42-43 divide the housing stock between central cities units and suburban residences to determine how the observed changes vary by location. Approximately 95 percent of all new construction between 1995 and 2002 took place in the suburb areas of Miami-Ft. Lauderdale. Rows 44-45 divide the housing stock by whether the occupants have moved in within the last two calendar years to determine if certain units consistently have high turnover and to see if high turnover units are more susceptible to loss.

[^4]
## Table 2

This table pertains to issues related to the physical quality of units. Row 1 repeats the analysis from row 2 in Table 1. All the subsequent rows are based on row 1.

Rows 2-3 look at whether the units have complete kitchens; that is, have an installed sink with piped water, a mechanical refrigerator, and built-in burners for the exclusive use of the occupants. Rows 4-5 look at whether the units have complete plumbing facilities; that is, hot and cold piped water, a flush toilet, and a bathtub or shower inside the structure for the exclusive use of the occupants. Rows 6-8 look at each of these requirements separately. In the 1995 AHS, the published reports separate out the "exclusive use" category; in the data used for this report, these units show up in row 8 . Rows 2-3, 4-5, and 6-8 attempted to separate out good units from the least desirable units, based on kitchen and bath equipment, to compare how they changed over the period.

Rows 9-13 pertain to how units obtain water and dispose of sewage.
Rows 14-19 look at units with serious problems. Rows 15-19 identify specific types of serious deficiencies. Row 14 counts the units having one or more of these deficiencies. Rows 20-25 look at units with moderate problems. Rows 21-25 identify specific types of deficiencies. Row 20 counts the units having one or more of these deficiencies. ${ }^{11}$ These rows are in the analysis to answer two questions: whether poor-quality units in one year are also poor-quality units in the other year, and whether poorer quality units are more likely to be lost. Both the forward-looking and backward-looking analyses clearly indicate that there is little continuity over the 7 years with respect to having serious or moderate physical problems. Fewer than 10 percent of the units with serious problems in 1995 had serious problems in 2002, and fewer than 5 percent of the units with serious problems in 2002 had had serious problems in 1995. The same is true for moderate problems, with fewer than 10 percent of units with moderate problems in one survey year having moderate problems in the other survey year. Approximately 5 percent of the occupied units had either serious or moderate problems in both years. The number of units with serious problems more than doubled between 1995 and 2002 (column C, row 15 in Forward-Looking Table 2 and Backward-Looking Table 2).

## Table 3

This table pertains to the characteristics of occupants. Row 1 repeats the analysis from row 2 in Table 1. All the subsequent rows are based on row 1.

Rows 2-3 look at the age of the householder. Rows 4-5 look at whether the household includes children. Rows 6-11 look at the race or ethnicity of the householder. Rows 12-14 look at three possible sources of household income. In all cases, the analysis seeks to

[^5]determine how stable the occupancy characteristics are over time, and what part of the market was served by units that lost between 1995 and 2002. In general, the CINCH weights tend to overestimate the number of units with Hispanic householders. Miami is one of the few sites where the CINCH weights underestimated the number of Hispanic householders. The number of units with Hispanic householders in Miami grew by almost 150,000 between 1995 and 2002. While Hispanic households account for approximately 40 percent of all households, they accounted for half of the newly constructed occupied units.

## Table 4

Table 4 pertains to tenure, income, and housing costs. Row 1 repeats the analysis from row 2 in Table 1. All the subsequent rows are based on row 1.

Rows 2-4 focus on tenure to determine the extent to which units change tenure characteristics and whether rental or owner-occupied units are more likely to be lost. Rental units in Miami were four times as likely to be lost due to demolition or disasters as owner-occupied units (1.1 percent versus 0.3 percent).

Rows 5-11 contain a partial rental dynamics analysis. ${ }^{12}$ Row 5 identifies non-market units, a class that includes subsidized units and units provided for no cash rents; for example, units given to maintenance or management personnel or to relatives. The remaining rows divide market rental units into affordability classes. In defining affordability, the analysis sets boundaries for each class based on the highest rent a household in an income group could afford without spending more than 30 percent of its monthly income on rent. Ideally there would be six categories in each metropolitan area:

- Extremely-low-rent units (rents affordable to households with incomes equal to 35 percent of area median family income).
- Very-low-rent units (rents not affordable at 35 percent, but affordable at 50 percent of area median family income).
- Low-rent units (rents not affordable at 50 percent, but affordable at 65 percent of area median family income).
- Moderate-rent units (rents not affordable at 65 percent, but affordable at 80 percent of area median family income).
- High-rent units (rents not affordable at 80 percent, but affordable at 100 percent of area median family income).
- Very-high-rent units (rents not affordable at 100 percent of area median family income).

[^6]For most metropolitan areas studied, the number of categories is fewer than six, because the Census Bureau had to place an upper limit on the rents reported in the public-use data to protect the confidentiality of respondents. Miami-Ft. Lauderdale has all six classes.

Rows 12-16 track rental units by household income; rows 22-26 track owner-occupied units by household income. ${ }^{13}$

Rows 17-21 identify owner-occupied units by total monthly housing costs. ${ }^{14}$
There appears to be a significant movement among units in both the costs to residents and the income of households. From Forward-Looking Table 4, only one of the rent categories (very low rents) has as many as 40 percent of its 1995 units in 2002, and only two of the monthly housing costs categories for owner-occupied units has as many as 40 percent of its 1995 units. Considering both renters and owners, only one of the income categories has as many as 40 percent. Backward-Looking Table 4 confirms this observation.

This movement is not surprising for four reasons: the categories are defined in nominal dollars not real dollars; there was substantial growth in nominal income over the 8-year period; while inflation was modest, there was some rental inflation over the period; and movement could be the result of units changing tenure or occupancy status. The rental dynamics analysis will look at the movement of units across tenure and occupancy statuses.

## Rental Market Dynamics

Table A expands the analysis in rows 5-11 in Forward-Looking Table 4 into a full rental dynamics analysis by examining in more detail what happened to the units in each row. In particular, the "present in 2002" and "change in characteristics" columns (column D and E in the CINCH tables) are disaggregated into the following options: each of the other rent affordability columns (new columns $D$ through $J$ ), owner-occupancy (new column $K$ ), and vacant or seasonal status (new column $L$ ). The remaining columns (columns F through K in the CINCH tables) are collapsed into a "Lost to stock" column (new column $M$ ). Table B does the same for the analysis of rows 5-11 in BackwardLooking Table 4.

From Table A, there were 470,300 rental units in Miami-Ft. Lauderdale in 1995. Of these, 28,650 had extremely low rents, 74,650 had very low rents, and 30,330 had low rents. From the 1995 rental stock, 148,220 were no longer rental in 2002; 77,930 were owner-occupied, 55,340 were vacant or seasonal, and 14,950 were out of the housing stock. Taken as a proportion of the units in 1995, movement into owner-occupancy was heaviest among the high-rent and very-high-rent categories, and losses to the stock were heaviest among extremely-low-rent units.

Table B shows there were 494,310 rental units in the Miami-Ft. Lauderdale metropolitan area in 2002, of which 162,930 were not rental units in 1995 . The new units came from units that had been owner-occupied $(59,510)$, units that had been vacant or in seasonal use $(68,460)$, newly constructed units $(30,860)$, and other additions $(4,100)$. Most of the formerly owner-occupied units were spread fairly evenly over the rent categories, and most of the newly constructed rental units went to the very-low-rent and the high-rent categories.

Looking at both tables, we see that the overall number of rental units increased by approximately 25,000 units between 1995 and 2002. The number of extremely-low-rent and very-low-rent units combined grew from approximately 105,000 in 1995 to approximately 180,000 in 2002.

Table A: Forward-Looking Rental Dynamics Analysis

| Forward looking | $C$ Number in 1995 | $D$ Non- market in 2002 | $\quad E$ Extremely low rent in 2002 | $F$ Very low rent in 2002 | $G$ Low rent in 2002 | $H$ Moderate rent in 2002 | $I$ High rent in 2002 | $J$ Very high rent in 2002 | K <br> Owneroccupied in 2002 | $L$ Vacant or seasonal in 2002 | $\begin{gathered} M \\ \text { Lost } \\ \text { to } \\ \text { stock } \end{gathered}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| Non-market | 72,150 | 27,110 | 6,980 | 6,980 | 7,800 | 820 | 410 | 0 | 10,270 | 8,630 | 3,150 |
| Extremely low rent | 28,650 | 1,640 | 8,630 | 6,160 | 2,460 | 0 | 0 | 0 | 4,520 | 2,880 | 2,360 |
| Very low rent | 74,650 | 2,880 | 11,500 | 36,140 | 5,750 | 820 | 0 | 0 | 8,210 | 6,980 | 2,360 |
| Low rent | 123,860 | 4,110 | 1,230 | 40,660 | 36,960 | 4,930 | 2,050 | 0 | 16,430 | 13,550 | 3,930 |
| Moderate rent | 96,430 | 820 | 2,050 | 6,570 | 26,970 | 21,670 | 2,460 | 1,230 | 19,200 | 14,270 | 1,180 |
| High rent | 46,260 | 410 | 820 | 1,640 | 1,230 | 18,480 | 7,700 | 820 | 9,860 | 4,110 | 1,180 |
| Very high rent | 28,300 | 820 | 0 | 0 | 410 | 1,640 | 4,520 | 5,750 | 9,450 | 4,930 | 790 |
| Column sum | 470,300 | 37,790 | 31,210 | 98,160 | 81,600 | 48,360 | 17,150 | 7,800 | 77,930 | 55,340 | 14,950 |

Table B: Backward-Looking Rental Dynamics Analysis

| Backward looking | $C$ <br> Number <br> in <br> 2002 <br> 5850 | $D$ Non- market in 1995 | $E$ <br> Extremely <br> low rent <br> in 1995 | $F$ Very low rent in 1995 | $\begin{gathered} \hline G \\ \text { Low } \\ \text { rent } \\ \text { in } 1995 \\ \hline \end{gathered}$ | $H$ Moderate rent in 1995 | $I$ High rent in 1995 | $J$ <br> Very high <br> rent in <br> 1995 | K <br> Owneroccupied in 1995 | $L$ Vacant or seasonal in 1995 | M <br> New construction | N <br> Other <br> additions |

## Appendix A - Internal and External Checks

For the CINCH analysis, we performed two tests of internal consistency:

- For each row, we tested whether the sum of possible outcomes (columns D though K in the forward-looking analysis and columns D through I in the backward-looking analysis) equaled the number of units present in the base year. In every case, equality was achieved except for differences created by rounding.
- Throughout the tables, various sets of rows are related to each other. For example, the year-built rows (13-23) in Table 1 are a disaggregation of the total stock in row 1. Similarly, rows 6 (Whites), 9 (Blacks), and 10 (Other race) in Table 3 are a disaggregation of row 1 (occupied households). In these cases, there should be equality between the parent row and the sum of the break-out rows for all columns except D and E . The difference between column D in the parent row and the sum of column D for the break-out rows should equal the negative of the difference between column E in the parent row and the sum of column E for the break-out rows. In every case, equality was achieved except for differences created by rounding.

Column B provides an external check of how well the CINCH weighting performed. In general, the CINCH estimates are within 5 percent of the AHS published totals and many of the CINCH estimates are very close to the AHS estimates. We have footnoted two places where our coding does not seem to produce the same results as the published estimates. We observed that the correspondence between the CINCH and published estimates were closer in the slower growing metropolitan areas. We also noticed that the CINCH weighting tends to underestimate the number of units built since 1989 and the number of Hispanic households.

## Appendix B - Weighting

CINCH separates the AHS samples in 1995 and 2002 into three components: units that exist and are part of the housing stock in both years (SAMES), units that are part of the 1995 housing stock but are not part of the 2002 housing stock (LOSSES), and units that are not part of the 1995 housing stock but are part of the 2002 housing stock (ADDITIONS). ADDITIONS are split into NEW CONSTRUCTION and RECOVERIES (structures that existed in 1995 but were not in the housing stock).

Because CINCH looks at various subsets of the housing stock, we need to know the characteristics of units and their occupants. Therefore, we can use only those SAMES observations that were interviewed in both years. For the same reason, we can use only those LOSSES that were interviewed in 1995 and those ADDITIONS that were interviewed in 2002.

For the forward-looking analysis, we started with the AHS pure weights and used the AHS weighted count in 1995 of SAMES to create weights for the interviewed SAMES. We used the AHS weighted count in 1995 of LOSSES to create weights for interviewed LOSSES. We then adjusted the weights of SAMES and LOSSES to equal the AHS published totals for occupied units, vacant units, and seasonal units in 1995.

For the backward-looking analysis, we started with the AHS pure weights and used the AHS weighted count in 2002 of SAMES to create weights for the interviewed SAMES. We used the AHS weighted counts in 2002 for NEW CONSTRUCTION and for RECOVERIES to create weights for interviewed NEW CONSTRUCTION and interviewed RECOVERIES. We then adjusted the weights for SAMES, NEW CONSTRUCTION, and RECOVERIES to equal AHS published totals for occupied units, vacant units, and seasonal units in 2002.

The logic behind the weighting and the procedures used to create the weights is explained in Weighting for CINCH and Rental Dynamics Analysis.

[^0]:    ${ }^{1}$ See http://www.huduser.org/datasets/cinch.html and http://www.huduser.org/datasets/ahs/ahsReports.html\#2.

[^1]:    ${ }^{2}$ Columns B and C will also match, except for rounding, in row 1 of Table 1 because row 1 is defined as the sum of rows 2 through 4.

[^2]:    ${ }^{3}$ If the owner or tenant both lives in a unit and conducts business out of the unit, the AHS considers the unit to be residential. So nonresidential means strictly no residential use.

[^3]:    ${ }^{4}$ The weighted numbers are rounded to the nearest 10 . The AHS publication rounds to the nearest 100 . We found that rounding to the nearest 10 worked better for the metropolitan sites. The weights were typically in the range of 100 to 300 and in many rows the numbers in columns F through K were small. With a weight of 149 , rounding to the nearest hundred would mean that one sample observation would be rounded to 100 , two sample observations to 300 , and three sample observations to 400 . Rounding to the nearest ten results in weighted totals of 150,300 , and 450 for these cases.
    ${ }^{5}$ This list does not contain a column for units added through mergers and conversions. The Census Bureau did not code the variable that would normally identify mergers and conversions in 2002 (REUAD=7 or 8).
    ${ }^{6}$ The Census Bureau did not code the variable that would normally identify mobile home move-ins in 2002 (REUAD=4). We estimated these from another variable (NOINT=13).

[^4]:    ${ }^{7}$ In general, the CINCH estimates exceed published AHS estimates for single-family detached units and fall short of the published AHS estimates for manufactured homes by roughly equal amounts.
    ${ }^{8}$ Row 13 is not included in the forward-looking tables, because the 1995 housing stock cannot contain units built after 1995 .
    ${ }^{9}$ We use REUAD=3 and not year built to identify new construction. For this reason, there are units built after 1995 that are not considered new construction. In addition, year built is obtained from the respondent interview and may be inaccurate.
    ${ }^{10}$ Because of small sample sizes in the losses and additions columns, we combined room categories that the published reports list separately.

[^5]:    ${ }^{11}$ For definitions of serious and moderate problems see pages 998 and 999 of the AHS Codebook, version 1.77, at http://www.huduser.org/intercept.asp?loc=/Datasets/ahs/AHS_Codebook.pdf.

[^6]:    ${ }^{12}$ The rental dynamics analysis is partial because it traces movement out of, but not into, particular rental classes. Tables A and B in the final section of this report contain a complete rental dynamics analysis.

[^7]:    ${ }^{13}$ Because of small sample sizes in the losses and additions columns, we combined income categories that the published reports list separately.
    ${ }^{14}$ Because of small sample sizes in the losses and additions columns, we combined cost categories that the published reports list separately.
